Abstract

This vignette introduces the use of the Bioconductor package `SDAMS`, which is designed for differential abundance analysis for metabolomics and proteomics data from mass spectrometry. These data may contain a large fraction of zero values and non-zero part may not be normally distributed. `SDAMS` considers a two-part semi-parametric mdoel, a logistic regression for the zero proportion and a semi-parametric log-linear model for the non-zero values. A kernel-smoothed likelihood method is proposed to estimate regression coefficients in the two-part model and a likelihood ratio test is constructed for differential abundant analysis.

1 Citation

The package SDAMS implements statistical methods from the following publication. If you use SDAMS in the published research, please cite:

Yuntong Li, Teresa W.M. Fan, Andrew N. Lane, Woo-Young Kang, Susanne M. Arnold, Arnold J. Stromberg, Chi Wang and Li Chen: A Two-Part Semi-Parametric Model for Metabolomics and Proteomics Data. (Manuscript)

2 Quick Start

This section show the most basic SDAMS work flow for a differential abundance analysis for metabolomics and proteomics data:

1. Create a SummarizedExperiment object using function createSEsetFromEnvir or create-SEsetFromCSV. In this section we use an example SummarizedExperiment set directly, which is an object of SummarizedExperiment class named exampleSumExpset contained in this package.
2. Perform a differential abundance analysis using SDA.

```
> library("SDAMS")
> data("exampleSumExpset")
> results=SDA(exampleSumExpset)
```

Here, the SummarizedExperiment class exampleSumExpset contained in the package is the proteomics dataset, which a matrix-like container for proteomics features with experimental subject grouping information. There are 560 features for 202 experimental subjects (0 for control and 1 for patient). This is a 10% subsample of the original dataset. Each row in this matrix repressents a proteomics feature. See Reference [1] for detailed information regarding this dataset.

3 Data Input

3.1 Create SummarizedExperiment object from csv.files

The proteomics or metabolomics data is stroed as a matrix with each row being a feature and each column corresponding to a subject. All data in this matrix are non-negative. Another information

required is the phenotype covariates. Here we focus on the binary grouping information, such as numeric 1 for control group and 0 for case group. But it can also be characters, such as "healthy" and "disease". To utlize `SDAMS` package, we should have two separate csv.files (for example 'feature.csv' and 'group.csv') as inputs for `createSEsetfromCSV` to creat a `SummarizedExperiment` object.

Note:

1. The 1st column in 'feature.csv' represents feature names and the 1st row represents subject codes.
2. The 1st column in 'group.csv' represents subject codes, for example, Subject1, Subject2....

The format for "csv.files" should looks like as Figure 1 and Figure 2:

Figure 1: Example of 'feature.csv' pattern

After creating the two csv.files, we need the paths for the two csv.files:

```
> path1 <- "/path/to/your/feature.csv/"
> path2 <- "/path/to/your/group.csv/"
```

Here for demonstration purposes, we use the data in the `SDAMS` package

```
> directory1 <- system.file("extdata", package="SDAMS", mustWork=TRUE)
> path1<-paste(directory1,"ProstateFeature.csv",sep="/")
> directory2 <- system.file("extdata", package="SDAMS", mustWork=TRUE)
> path2<-paste(directory2,"ProstateGroup.csv",sep="/")
```

then use the function `createSEsetFromCSV` after loading the `SDAMS` package.

Figure 2: Example of 'group.csv' pattern

```
> library("SDAMS")
> exampleSEset1 = createSEsetFromCSV(path1,path2)
> exampleSEset1

class: SummarizedExperiment
dim: 560 202
metadata(0):
assays(1): counts
rownames(560): 93922 87209 ... 180624 130855
rowData names(0):
colnames(202): 9512 9963 ... 49341 49586
colData names(1): grouping
```

The feature data and grouping information can be accessed using SummarizedExperiment command:

```
> head(assay(exampleSEset1)[,1:10])

          9512    9963   9965   9975    9979   9997 10015   10034   10044 10047

```

```
> head(colData(exampleSEset1)$grouping)
```

```
[1] 0 1 1 1 1 1
```

3.2 Create SummarizedExperiment object from R global environment

If the two datasets have been already claeaned and loaded into the R global environment, we can use
createSEsetFromEnvir to create a SummarizedExperiment object.

```
> set.seed(100)
> featureInfo = matrix(runif(800,-2,5),ncol = 40)
> featureInfo[featureInfo<0] = 0
> rownames(featureInfo) = paste("feature",1:20,sep = '')
> colnames(featureInfo) = paste('subject',1:40,sep = '')
> groupInfo = data.frame(grouping=matrix(sample(0:1,40,replace = TRUE),ncol = 1))
> rownames(groupInfo)=colnames(featureInfo)
> exampleSEset2 = createSEsetFromEnvir(feature = featureInfo,group = groupInfo)
> exampleSEset2
```

```
class: SummarizedExperiment
dim: 20 40
metadata(0):
assays(1): counts
rownames(20): feature1 feature2 ... feature19 feature20
rowData names(0):
colnames(40): subject1 subject2 ... subject39 subject40
colData names(1): grouping
```

```
> head(assay(exampleSEset2)[,1:10])
```

```

4 Data Analysis

Finally, we perform differential abundance analyais using `SummarizedExperiment` object created in the last section. This can be done by using function `SDA`. And a list with point estimates, p-values, q-values and corresponding feature names is returned. Below is results generated by using the `SummarizedExperiment` object exampleSEset1.

```
> results = SDA(exampleSEset1)
> head(results$gamma)

[1]  0.1100009  0.8629447 -0.7151261  0.2876821 -0.1251631  0.6292037
